May 1, 2007

Abstract

This paper develops an endogenous growth framework with externalities due to learning by doing and trade openness to show that these externalities are significant for 6 Asian countries. The estimated parameters of the augmented production functions are used to compute the steady state growth rates for Singapore, Malaysia, Thailand, Hong Kong, Korea and the Philippines. A few broad policies to improve these steady state growth rate are suggested.

JEL Classification: N1, O1, O4, O11

Keywords: Endogenous Growth, Learning by Doing, Trade Openness, Steady State Growth Rate, Newly Developing Asian Countries.

*I am grateful to Professor Ron Smith of Birkbeck College, London (UK) and Professor Alfred Greiner of Bielefeld University (Germany) for many critical comments and helpful suggestions. However, all remaining errors are my responsibility. I am also greatly indebted to my colleagues Rup Singh and Gyaneshwar Rao. Rup Singh has collected the data, did the proof reading and keyed in LaTeX tables in an earlier version of this paper. He also found a typographical error in the derivation of one of the steady state growth equations. Gyaneshwar Rao spotted several typos.

“In a world full of countries desperately trying to get richer, the winners become influential models for the rest. But exactly what is it that accounts for their success? This isn’t merely an abstract academic debate. The consensus tends to get built into the policies of dozens of ambitious countries, affecting patterns of world trade and much else.” *Washington Post*, quoted by Sarel (1995).

1 Introduction

Endogenous growth models (ENGMs) are useful to answer two important questions viz., what factors determine the long run growth rate of an economy and whether this growth rate can be improved through policy. Although there is a large volume of empirical work on ENGMs with cross-section data, empirical works with country specific time series data are limited and often use *ad hoc* specifications.¹ Country specific time series studies are important because it is hard to justify the basic assumptions of the cross-section studies that the forces of economic growth and the underlying structural parameters are the same for all countries and at all times. Furthermore, while cross-section studies may give some insights into growth enhancing policies, they are not useful to estimate country specific steady state growth rates (SSGRs) and identify policies to improve the SSGR. To the best of our knowledge there are no country specific estimates of SSGRs and their determinants.² They are generally inferred from plots of growth rates and trends if these data exist for very long periods.

Jones (1995) is one of the earliest to examine the use of ENGMs with country specific time series data. He has used the reduced form VAR methodology and was critical of the use of ENGMs for the USA and the OECD countries. Subsequently Kocherlakota and Kei-Mu Yi (1996) have used data from the USA and a more comprehensive VAR framework to examine if key policy variables affect the growth rate. They found that only the non-military equipment investment and non-military structural investment have some effects on the longrun growth rate. Chao-Hsi Huang (2002) applied Kocherlakota and Kei-Mu Yi’s

¹These are *ad hoc* in that annual growth rate or output is simply regressed on a set of variables, and at times on only one variable, which the investigator believes are important. However, It is hard to accept that annual growth rate or level of output is a good measure of their steady state values. Since this is a widespread practice, it is unnecessary to lengthen the list of reference with citations.

²Perhaps these estimates are similar in importance to country specific estimates of the natural rate of unemployment.

approach to 11 Asian countries and found no support for ENGMs. In contrast Greiner, Semler and Gong (2004) have used structural models. They have estimated, with non-linear dynamic methods, some key structural parameters in the canonical ENGMs of Uzawa-Lucas where accumulation of human capital is the key growth force, Romer (1990) in which knowledge and R&D are the growth enhancing factors and Barro (1990) in which public expenditure on infrastructure is the growth inducing factor. The estimated structural parameters are related to the optimal saving and investment rates, evolution of the stocks of capital and knowledge, and the parameters of the augmented production functions. Using mainly U.S. and German data they found that accumulation of physical, human and knowledge capital, externalities and public expenditure on infrastructure seem to be the main forces of growth. However, the importance of these growth forces may be different at different stages of development because the underlying structural parameters are not the same in all the countries and at all times. They also found that it is difficult to analyze, with time series data, these forces, at once, with a single comprehensive ENGM and estimate their individual effects. Therefore, the only pragmatic option seems to be to estimate ENGMs with a few relevant country and development-stage specific factors at a time.³

This paper is mainly motivated by the aforesaid findings and in particular those of Greiner et. al. It develops a simple framework based on the ENGM of Romer (1986) where technical progress (TFP) depends on the “manna from heaven” variety of externalities. Such externalities are considered important for the developing countries, e.g., the newly industrialising Asian countries, which are at an early stage of development compared to the developed western countries. Our approach differs from Jones, Kocherlakota and Kei-Mu Yi and Huang in two respects. First, we use a structural approach to analyze the significance of two important externalities in the augmented production function. Second, the effects of these externalities on the steady state growth rate (SSGR) are computed with the estimated parameters of the production functions. Data from Singapore, Malaysia, Thailand,

³In order to get meaningful results Greiner et. al had to remove the scale effects and introduce non-linear effects. This is interesting for two reasons. First, Jones’ (1995) finding that these scale effects are absent does not necessarily invalidate ENGMs or their variants. Second, it seems necessary to make some modifications to the implied theoretical specifications of the ENGMs. In our empirical work we found it necessary to introduce non-linear effects for Korea and use grid search to estimate the share of profits.

Hong Kong, the Philippines and Korea for the period 1970 to 2004, are used to illustrate our approach.

Since the externalities in our model do not need additional investments by firms and households, it is felt that it is not necessary to estimate the elaborate structural models of Greiner et. al.⁴ As stated earlier our externalities are the “manna from heaven” variety viz., learning by doing (LBD) and trade openness (TRADE).⁵ LBD is proxied with the stock of capital and TRADE with the ratio of exports plus imports to output. Use of capital as a proxy is similar in Romer (1986) where LBD is proxied with the investment ratio.⁶

The structure of this paper is as follows. Section 2 develops our specifications. Empirical results on the augmented production functions and estimates of the steady state growth rate are presented first for Singapore in Section 3 because the cointegration test results are more robust for this country. To conserve space the insights from analyzing the Singapore data are used in Section 4 to estimate the augmented production functions and derive the SSGRs for the other 5 Asian countries. Section 5 presents alternative estimates of SSGRs and examines the sensitivity of the estimates in the previous section. Finally, conclusions and limitations are stated in Section 6.⁷

⁴Preliminary results showed that our approach is promising for China, India, Indonesia, Pakistan and Sri Lanka. However, although the coefficients of the externalities have the expected signs, they were statistically insignificant. This may be due to the late start of liberalization policies in these countries. Further work is under progress.

⁵We have ignored another important externality viz., human capital accumulation for two reasons. In preliminary investigations its coefficient was not well determined and insignificant perhaps due to multi-co-linearity. Furthermore, rapid structural changes and aggressive export policies—the main features of the countries in our sample—seem to have helped the East Asian countries to accumulate human capital through on-the-job training instead of formal schooling; see Lucas (1988) and Grossman and Helpman (1991). Exports allow rapid changes in the mix of goods while protectionist policies encourage a mix to satisfy domestic consumers. Frankel (1997, pp.10-12) has an excellent summary of the channels through which both exports and imports can improve the growth rate of a country; see also Arnold (1994) and Greiner et.al., (2004). Countries like India, which for a long time pursued protectionist trade and bureaucratic investment policies, ended up with a mix of goods without variety and sophistication. Of an Indian made car it is often said that virtually all of its parts make noise except the horn.

⁶At an empirical level DeLong and Summers (1991), Levine and Renelt (1992) and Sala-i-Martin (1997) have shown that growth rate depends on the investment rate.

⁷The controversy on the East Asia Growth Miracle seems to have ignored the effects of LBD. Frankel (1997) and Sarel (1995) summarized this controversy with a list of potential determinants of SSGRs. High export and investment ratios

2 Specification

Externalities in our model are similar to those in Rebelo (1991) and Romer (1986) where increases in TFP of firms are like “manna from heaven” i.e., firms need not use additional resources to increase output. Some examples of these externalities are LBD of Arrow (1962), TRADE and public expenditure on structural overheads etc. Another feature of this approach is that while at the firm level there are constant returns to scale, at the aggregate level there are increasing returns. This feature preserves the assumption of perfect competition in the product markets.

Let the Cobb-Douglas production function with constant returns for a *representative* firm i and with the assumption that TFP at the firm level depends on the aggregate capital stock be:

$$Y_{it} = K_{it}^{\alpha} (A_{it} L_{it})^{(1-\alpha)} \epsilon_{it} \quad (1)$$

$$A_{it} = B_t K_t^{\phi} \quad \text{where } \phi \geq 0 \quad (2)$$

where Y is output, K is capital, L is employment and ϵ is an error term such that $\ln(\epsilon_i) \sim N(0, \sigma^2)$. B here stands for the stock of knowledge which depends on autonomous factors. Therefore, $\Delta \ln B$ is the rate of growth of autonomous TFP. B can be assumed to be constant ($\Delta \ln B = 0$) or to grow at a constant autonomous rate of g i.e.,

$$B_t = B_0 e^{gt} \quad (3)$$

where B_0 is the initial stock of knowledge. $\Delta \ln B$ thus captures the effects of other missing and trended variables affecting A and similar to A in the Solow (1956) model. Substituting (3) for A in (2) gives, through aggregation, the aggregate production function.⁸

are considered to be important, but there is no quantitative evidence on their significance. Sarel also discusses reverse causality without resolving this issue. So at the end of this debate no one knows the quantitative significance of factors in the East Asian Growth Miracle.

⁸To estimate the aggregate production function it is necessary to measure the variables as geometric means i.e., $\ln Y = (1/n) \sum \ln Y_i$ etc. However, such aggregate data are not available. When the aggregate variables are summations, strictly speaking an aggregate production function exists only if the production function is separable. But neither the CD nor CES production functions are separable. Therefore, the *representative firm* assumption and the assumption that factors of production are perfectly mobile between firms are necessary.

$$\begin{aligned} Y_t &= K_t^{(\alpha+\phi(1-\alpha))} (B_t L_t)^{(1-\alpha)} \\ &= B_0^{1-\alpha} e^{g_t(1-\alpha)} K_t^{(\alpha+\phi(1-\alpha))} L_t^{(1-\alpha)} \epsilon_t \end{aligned} \quad (4)$$

where $\epsilon = \sqrt[n]{(\prod_1^n \epsilon_i)}$ and $\ln(\epsilon) \sim N(0, \sigma^2)$. In equation (4) when $\phi = 0$ there are constant returns at the aggregate level. Otherwise returns to scale are $\alpha + (1 - \alpha)(1 + \phi) > 1$.⁹

Alternative assumptions about A are possible. For example, if A depends on other factors with externalities, besides K , such factors can also be included. If trade openness (TRADE) has an externality, which is important for the East Asian countries, A may be specified as:

$$A_t = B_0 K_t^{\phi_1} TRADE_t^{\phi_2} \quad (5)$$

or

$$= B_0 e^{(g_1+g_2 TRADE_t) \times t} K_t^{\phi} \quad (6)$$

In equation (6) TRADE increases permanently the growth rate whereas in (5) it has only permanent level effects.¹⁰ Using the previous procedures, (5) gives the following production function:

$$Y_t = B_0^{1-\alpha} e^{g_t(1-\alpha)} TRADE_t^{[\phi_2(1-\alpha)]} K_t^{(\alpha+\phi_1(1-\alpha))} L_t^{(1-\alpha)} \quad (7)$$

The production implied by (6) is

$$Y_t = B_0^{1-\alpha} \left[e^{(1-\alpha)(g_1+g_2) TRADE_t} \right] K_t^{(\alpha+\phi(1-\alpha))} L_t^{(1-\alpha)} \quad (8)$$

and this is the same as (4) except that g is computed as $(g_1+g_2 TRADE)$. All the later derivations based on (4) hold for (8). These production functions also show the implied parameter restrictions.

⁹A characteristic of the ENGM is that capital has constant returns, where as in our model this assumption is not retained. Therefore, our model is referred to as a framework based on ENGMs. I thank Professor Greiner for pointing the need for this interpretation.

¹⁰Sarel (1995, p.14) supports the growth effect in equation (6). According to him

“Among the many suggested determinants of growth in East Asia, the investment rate and the export orientation, in particular, are held in very high esteem. Frequently, they are called the ‘engines of growth’, meaning that these activities are considered not only to contribute directly to growth, but also to generate spill-over effects to the rest of the economy.

Furthermore, it is reasonable to say that whether a potential growth improving variable has permanent growth and/or level effects is an empirical issue.

2.1 Steady State Output and Growth Rate

For the derivation of the steady state output and its growth rate we shall use (4). There is a steady state solution only when $\phi < 1$. If $\phi \geq 1$, there is no steady state because there are no diminishing returns to K and ΔK does not become zero, which is the definition of the steady state. Therefore, in the following derivations it is assumed that $\phi < 1$.¹¹ Since B is similar to A in the standard Solow (1956) model, dividing Y and K with L and B gives $\tilde{y} = (Y/BL)$ and $\tilde{k} = (K/BL)$. Equation (4) can be expressed as:

$$\begin{aligned} \left(\frac{Y_t}{B_t L_t} \right) &= \left(\frac{K_t}{B_t L_t} \right)^\alpha K_t^{\phi(1-\alpha)} \\ \tilde{y}_t &= \tilde{k}_t^{\alpha+\phi(1-\alpha)} (B_t L_t)^{\phi(1-\alpha)} \end{aligned} \quad (9)$$

The evolution of capital is also the same as in the Solow (1956) model, i.e.,

$$\frac{\Delta \tilde{k}_t}{\tilde{k}_t} = \frac{s \tilde{y}_t}{\tilde{k}_t} - \delta \quad (10)$$

where δ is the rate of depreciation. In equilibrium $(\Delta \tilde{k}/\tilde{k}) = 0$. Therefore, solving for the equilibrium value of \tilde{k} and substituting into the production function in (9) gives the following steady state output.¹²

¹¹Furthermore, there is no empirical evidence for increasing or constant returns to capital. Greiner et. al. (2004) have to remove such scale effects in their empirical work. Jones (1995) also found that there is no evidence for increasing or constant returns even for knowledge capital (R&D expenditure). Therefore, it is appropriate perhaps to call our approach as a framework based on ENGMs. This raises the possibility of four types of growth models for empirical work viz., the neoclassical Solow model, the extended neoclassical model of Mankiw, Romer and Weil (1992), a set of canonical endogenous growth models with scale effects and variants of such endogenous growth models without scale effects but significant growth effects. In light of some important findings (with time series data) by Greiner et. al. (2004), Jones (1995) and Kocherlakota and Kei-Mu Yi (1996) the last category seems to be promising in empirical work with time series data. One may also call these models as extended Solow models. While in the Mankiw, Romer and Weil extension there are only level effects, in the new extended Solow models there are significant growth effects which may eventually converge due to a constant rate due to their non-linear effects.

¹²Note that when $\phi = 0$ this equation reduces to the standard solution in the Solow model.

$$\tilde{y}^* = \left(\frac{s}{\delta + n + g} \right)^{\frac{\alpha + \phi(1-\alpha)}{(1-\alpha)(1-\phi)}} (BL)^{\frac{\phi}{1-\phi}} \quad (11)$$

From equation (11) we can solve for the steady state rate of growth of per worker income, noting that $(\Delta y/y) \equiv (\Delta \tilde{y}/\tilde{y}) + g$, where g is autonomous rate of growth of B .

$$\frac{\Delta y}{y} = \frac{g}{1-\phi} + \frac{\phi n}{1-\phi} \quad (12)$$

If $\phi = 0$ i.e., there are externalities, the above growth rate reduces to the exogenous growth rate g in the Solow model. The steady state output and growth equations when TFP depends on TRADE as in equation (6) are the same as above except that $g = g_1 + g_2 \text{TRADE}$. On the other hand if the externality due to TRADE has only level effects as in equation (5), steady state growth is:

$$\frac{g + \phi_1 n + \phi_2 \theta}{(1-\phi_1)} \quad (13)$$

where θ is the rate of growth of TRADE.

Since equations like (12) and (13) are steady state equations, they can be estimated with cross section data with 15 or 20 year average values of the variables. Country specific annual time series data are not appropriate for estimating these steady state growth equations because a year long duration is inadequate for the economy to attain its steady state. However, annual time series data can be used to estimate the long run production functions with time series methods. Therefore, the steady state growth rates in equations (12) and (13) can be computed with the estimated parameters from the production functions.

For estimation purpose it is convenient to rearrange the production functions (4), (7) and (8), respectively, as follows.

$$\tilde{y}^* = \left(\frac{s}{\delta + n + g} \right)^{\frac{\alpha}{1-\alpha}}$$

$$\begin{aligned} \ln y_t = & (1 - \alpha)\ln B_0 + (1 - \alpha)gt + [\alpha + \phi(1 - \alpha)]\ln k_t \\ & + \phi(1 - \alpha)\ln L_t \end{aligned} \quad (14)$$

$$\begin{aligned} \ln y_t = & (1 - \alpha)\ln B_0 + (1 - \alpha)gt + (1 - \alpha)\phi_2\ln TRADE_t \\ & + [\alpha + \phi_1(1 - \alpha)]\ln k_t + \phi_1(1 - \alpha)\ln L_t \end{aligned} \quad (15)$$

$$\begin{aligned} \ln y_t = & (1 - \alpha)\ln B_0 + (1 - \alpha)(g_1 + g_2\text{TRADE}_t)t \\ & + [\alpha + \phi(1 - \alpha)]\ln k_t + \phi(1 - \alpha)\ln L_t \end{aligned} \quad (16)$$

where $y = (Y/L)$ and $k = (K/L)$.

In our empirical work, however, the specification in equation (16), where TRADE has a permanent growth effect, is found to be the best for all the six countries although for Korea it was necessary to use a variant of (16) in which TRADE has non-linear effects.

3 Empirical Estimates for Singapore

In Table 1, three alternative estimates of the production function for Singapore are given. Singapore is first selected because the cointegration tests are more robust. Of the three specifications in equations (14), (15) and (16) the specification in (16), where TRADE has permanent growth effects, was found to be the best and gave plausible results. To conserve space, only the estimates of this equation and its variants are reported in Table 1. In Table 2 similar estimates of the specification in (16) are given for Malaysia, Thailand, Hong Kong, the Philippines and Korea. Data from 1970 to 2004 are used for estimation of these six countries. Definitions of the variables and sources of data are in the Appendix. The LSE-Hendry GETS technique, with the non-linear two stage instrumental variable method, is used to minimize endogenous variable bias and also to utilize the parameter restrictions. The Ericsson and McKinnon (2003) test (EM) is used to test for cointegration. All the variables are pre-tested, first for Singapore, for unit roots with the ADF test. Except the log of capital per worker ($\ln k$), other variables are found to be $I(1)$ in levels and $I(0)$ in their first differences. We have used two alternative unit root tests viz., KPSS, where the null is that the variable is stationary and the ERS test which has more power against the unit root null. These tests showed that $\ln k$ is $I(1)$ in levels and $I(0)$ in its first differences. Unit root tests for the other countries will be discussed in the next

section.¹³

First, the standard CD production function, without externalities, is estimated for Singapore and the results are in column (1) of Table 1 as equation (I).¹⁴ The final form with the current and lagged first differences of the variables is selected with the general to specific approach and with the variable deletion tests. The GETS specifications for the other equations in Table 1 and Table 2 are similar and can be easily inferred by changing the error correction part. To conserve space these details are not reported. Equation (I) serves as the baseline equation for comparisons. The estimates of this equation are satisfactory in that all of its coefficients are correctly signed and significant at the 5% level, except Δk_{t-1} (not shown) which is significant at 10%. The summary χ^2 tests show that serial correlation (χ_{sc}^2), functional form misspecification (χ_{ff}^2), and non-normality in the residuals (χ_{nn}^2) are not significant at the 5% level. The Sargan test validates the selected instruments. The coefficient of trend, which is the steady state growth rate in the Solow model, is about 4% and seems a bit high. The share of profits (α) at 0.21 seems a bit low. However, neither estimate is implausible.¹⁵

Estimates of the specifications in equations (14), without externalities due to TRADE and (15) in which both capital and TRADE (level effects only) have externalities were disappointing in that the estimated share of profits (α) turned out to be low (about 0.1) and insignificant. Therefore, a grid search is used for α in the range of 0.2 (as found in the baseline equation (I)) to 0.5. In the search procedure, estimates of equation (16) are found to be more satisfactory. In equations (14) and (15) one or another externality is found to be negative and/or insignificant. Estimates of the specification in equation (16) with the constraint that $\alpha = 0.24$ yielded the best results and are reported in column 2 as equation (II). Finally, since trend is insignifi-

¹³Details of these test results can be obtained from the author.

¹⁴The full GETS specification of this equation with the error correction term (*ECM*) in the square brackets is as follows:

$$\begin{aligned} \Delta y_t = & -\lambda[\ln y_{t-1} - (\text{intercept} + gt + \alpha k_{t-1})] \\ & + \text{first differences of the variables and their lags.} \end{aligned}$$

where λ is the speed of adjustment of the error correction process.

¹⁵The dynamic adjustment part, not reported to conserve space, consists of $\Delta \ln k_t, \Delta \ln k_{t-1}, \Delta \ln L_t$ and $\Delta \ln y_{t-1}$. The instruments used are Intercept, Trend, $\ln y_{t-1}, \dots, \ln y_{t-4}, \ln k_{t-1}, \dots, \ln k_{t-4}, \ln \text{TRADE}_{t-2}, \Delta \ln \text{TRADE}_{t-1}$

cant in equation (II) this equation is re-estimated by constraining that the autonomous growth rate is zero and given as equation (III). The summary statistics of the two ENGM equations are satisfactory.

A comparison of the \bar{R}^2 of the standard Solow equation of about 0.5 with the other 2 equations of about 0.6 shows that the ENGM equations have an improved fit of 18%.¹⁶ Furthermore, the EM cointegration test showed that the null of no cointegration can be rejected at the 5% level for the 2 ENGM equations. The sample size adjusted 5% absolute critical value (CV) for (II) is 4.269 and its test statistics given by the absolute t -ratios of λ exceed this CV. But the null of no cointegration cannot be rejected for equation (I). Therefore, it can be said that the ENGM equations are preferable to the Solow equation.¹⁷

¹⁶Formal statistical tests, based on the Z test, showed that there is no significant difference between these correlation coefficients, unless these estimates hold in a sample of about 300. Since our sample size is small, it is not possible to say that the correlation coefficients of the 2 ENGMs are significantly higher than equation (I) of the Solow model. However, asymptotically they are better.

¹⁷The estimate of equation (II), is not fully reported in Table-1 to avoid formatting problems. Only the estimates of crucial parameters are reported in Table 1. However, the full estimate of (II) is as follows:

$$\begin{aligned} \Delta \ln y_t = & -0.676 \left[\ln y_{t-1} - \left(2.734 - 0.002 T \right. \right. \\ & (9.673) \qquad (0.265) \quad (5.122) \\ & + 0.113 TRATIO_{t-1} T + 0.24 \ln k_{t-1} \\ & (5.121) \qquad (c) \\ & \left. \left. + 0.239 (\ln l_{t-1} + \ln k_{t-1}) \right) \right] \\ & (2.485) \\ & + 0.902 \Delta \ln k_t + 0.132 \Delta TRATIO_t \\ & (2.996) \qquad (3.224) \end{aligned}$$

t -ratios are reported below the coefficients in the parentheses and the constrained coefficient estimate is indicated with (c). Estimates of (III), in which the autonomous growth rate is constrained to be zero, are similar with minor changes.

Table 1: Externalities in Singapore

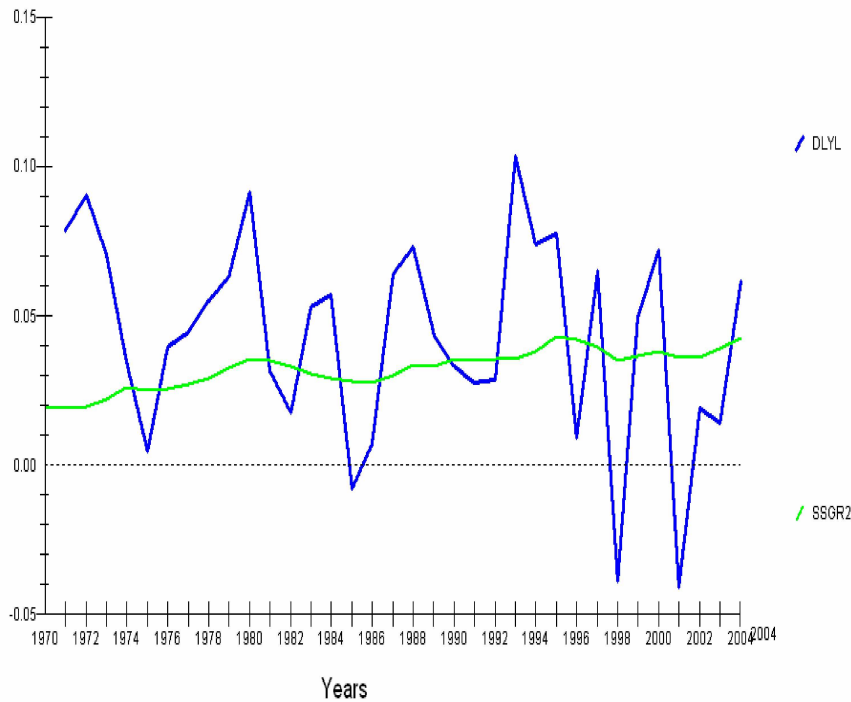

Variable	(I)	(II)	(III)
Const.	7.271 (12.21)*	2.734 (1.51)	3.084 (2.43)*
Trend	0.039 (35.89)*		
λ	-1.044 (4.06)*	-0.676 (9.67)*	-0.691 (10.06)*
α	0.205 (4.18)*	0.240 (c)	0.240 (c)
g_1		-0.002 (0.27)	
g_2		0.011 (5.12)*	0.011 (6.89)*
ϕ		0.239 (2.48)*	0.220 (3.35)*
R^2	0.508	0.594	0.610
χ^2_{sc}	1.244 (0.27)	1.098 (0.30)	1.059 (0.30)
χ^2_{ff}	2.473 (0.12)	0.020 (0.82)	0.032 (0.86)
χ^2_{nn}	0.156 (0.93)	0.388 (0.82)	0.350 (0.84)
<i>Sargan</i> χ^2	1.344 (0.85)	2.615 (0.86)	2.759 (0.91)

Notes: The t -ratios (White adjusted) are below the coefficients and p -values are below the χ^2 tests statistics. 5% and 10% significance are indicated with * and **, respectively. Constrained estimate is indicated with (c).

Among the 2 ENGM equations the estimate of equation (III) is marginally better because of the improved t -ratios of the coefficients due to a small increase in the degrees of freedom. The estimates of this equation imply that externalities due to openness and LBD are significant in Singapore. The computed steady state growth rate of output per worker (SSGR) in Singapore is computed with the average values of TRADE and the rate of growth of employment and this is

3.3%; see equation (12) noting that $g = g_1 + g_2 TRADE$. Note that the autonomous growth rate (g_1) is zero. These findings are in contrast to the well known finding of Young (1995) that Singapore's TFP and therefore SSGR were negligible at 0.2% during 1966 to 1990. This may be due to the neglect of externalities by Young (1995).

Figure 1: Steady State Growth of Singapore

The plot of SSGR for Singapore and the actual rate of growth of per worker output is in Figure 1. The values of the SSGR are computed here with the actual values of TRADE and the rate of growth of employment, in contrast to with their average values in the previous paragraph.

It can be seen that the SSGR has shown a mild upward trend until the financial crisis during 1996-1997. As Singapore has evolved from an underdeveloped to a newly industrialized country, its SSGR seems to have improved marginally. An OLS equation showed that the trend in the SSGR is 0.0006 per year.

The contribution of LBD of 0.8 percentage points to SSGR is 24%

of SSGR. The dominant contribution of 2.5 percentage points which is 76% of the SSGR is due to Singapore's trade openness policy. These findings for Singapore and the findings for the other countries are summarized in Table 3. Although the SSGR is high in Singapore, a policy implication of our model is that there is scope to improve by improving on the job training. A further 25% increase in the effectiveness of LBD programmes could increase Singapore's SSGR by another 0.5% points.

4 Other Asian Countries

We have estimated the specifications in equations (14) to (16) for Malaysia, Thailand, Hong Kong, Philippines and Korea. However, only the specification in (16) used for Singapore (in equations (II) and (III) of Table 1) gave plausible results for these countries. All the variables are tested for unit roots with ADF, KPSS and ERS tests. As for Singapore $\Delta \ln k$ was $I(0)$ only in the KPSS and ERS tests for these 5 countries. ADF test showed that the remaining variables are all $I(1)$ in levels and $I(0)$ in their first differences.

The coefficient of trend, which is the autonomous growth rate, was also insignificant in these 5 countries. Therefore, in Table 2 only the constrained estimates, given in (III) of Table 1, are reported for these 5 countries as equations (IV) to (VIII). The share of profits has to be grid searched again and values around 0.24 gave the best results, except for Korea where the near stylized value of 0.3 gave plausible results. We also faced some convergence problems with the Korean data and eventually obtained good results after introducing non-linear effects for TRADE. In these 5 equations the summary χ^2 test statistics are insignificant and the EM cointegration test rejected the null hypothesis of no cointegration. The \bar{R}^2 s are also satisfactory.

4.1 Malaysia

In equation (IV) for Malaysia the share of profits with grid search is 0.25. The estimates of the other parameters imply a SSGR of 1.5% which is half of Singapore's. The contribution of trade openness to SSGR at 1% points, which is also half of Singapore's, implies that Singapore has benefited better from production technologies and management techniques from its trading partners than Malaysia. Similarly ϕ at 0.13 indicates that the effectiveness of LBD on Malaysia's SSGR is

about 60% of its effectiveness in Singapore. The ratios of the contributions of trade and LBD to the SSGR, respectively, are 68% to 32%. Therefore, there is scope to improve Malaysia's SSGR through more effective LBD programmes. By increasing TRADE and LBD by 25% the SSGR of this country can be improved by another 0.5% points from 1.5% to 2%.

The average rate of growth of output per worker during 1970-2004 and 2000-2004 are, respectively, 3.6% and 2%, implying that currently Malaysia is not far from its SSGR of 1.5%. The plot of the actual rate of growth of per worker output and SSGR (computed with the actual values of TRADE and employment growth) is shown in Figure 2. There is a mild upward trend of 0.0004 in the SSGR which is encouraging.

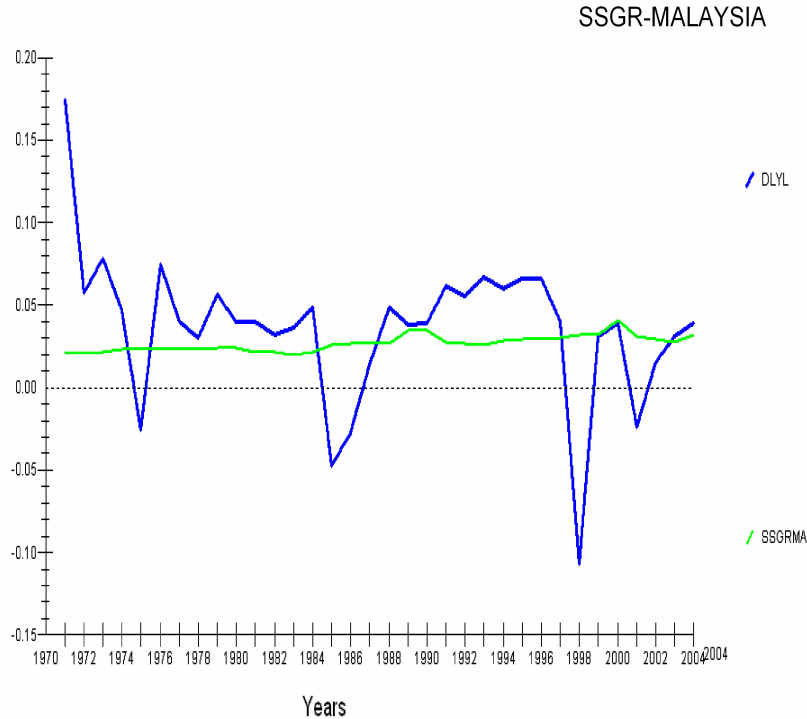

Table 2: Externalities in Other Asian Countries

Variable	(IV)	(V)	(VI)	(VII)	(VIII)
Const.	5.654 (10.19)*	2.080 (1.99)**	3.403 (5.35)*		-4.188 (9.18)*
λ	-0.760 (12.98)*	-0.506 (6.42)*	-0.713 (10.46)*	-0.371 (3.23)*	-0.477 (4.77)*
α	0.250 (c)	0.240 (c)	0.240 (c)	0.260 (c)	0.300 (c)
g_2	0.006 (10.66)*	0.012 (5.11)*	0.004 (6.80)*		0.006 (3.49)*
ϕ	0.132 (6.14)*	0.285 (7.48)*	0.292 (12.26)*	0.357 (102.63)*	0.289 (11.16)*
R^2	0.614	0.620	0.532	0.345	0.522
χ^2_{sc}	1.644 (0.20)	1.898 (0.17)	0.215 (0.64)	0.009 (0.93)	0.019 (0.91)
χ^2_{ff}	1.719 (0.19)	11.733 (0.00)*	0.048 (0.83)	0.151 (0.70)	2.545 (0.11)
χ^2_{nn}	0.448 (0.80)	2.916 (0.23)	0.150 (0.93)	0.224 (0.89)	3.762 (0.15)
Sargan χ^2	8.411 (0.30)	11.610 (0.11)	17.246 (0.14)	3.617 (0.82)	6.263 (0.51)

Notes: The t -ratios for the coefficients and the p-values for the χ^2 tests are in parenthesis. 5% and 10% significance

are indicated with * and **, respectively. Constrained estimate is indicated with (c).

Figure 2: Steady State Growth of Malaysia

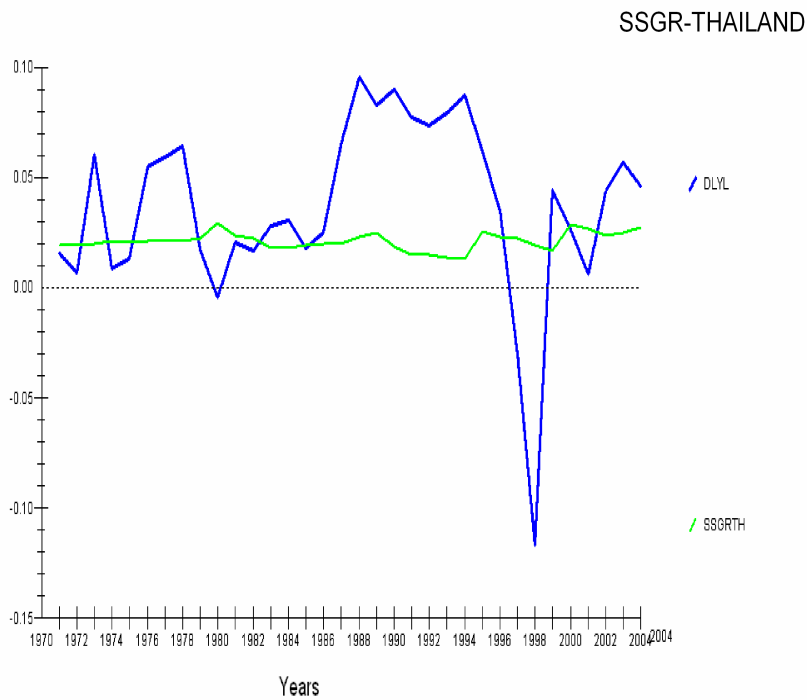

4.2 Thailand

The estimate for Thailand is in equation (V). A profit rate of 0.24 gave the best results. The computed parameters imply a SSGR of 2.3%. The contributions of LBD and TRADE to SSGR seem to be of equal importance, contributing about 1% points each to SSGR. To increase its SSGR by another 0.5 points to 2.8%, Thailand needs to introduce significantly more liberalized trade policies to increase the mean value of TRADE from about 0.7 to above 1.

The average rate of growth of output per worker is high at 3.7% during 1970-2004 and declined only marginally during 2000-2004 to 3.6%. Therefore, this country is growing above its SSGR mainly due to the transitory effects of increased investment ratio. Investment boom in Thailand started in the late 1980s and investment ratio reached near 50% until the Asian financial crisis in 1997-1998. During the investment boom period, the rate of growth of per worker income was

as high as 10%. The SSGR for this country, with the actual values of TRADE and employment growth, and the actual rate of growth of per worker income is in Figure 3 and it shows a mild upward trend of about 0.0001.

Figure 3: Steady State Growth of Thailand

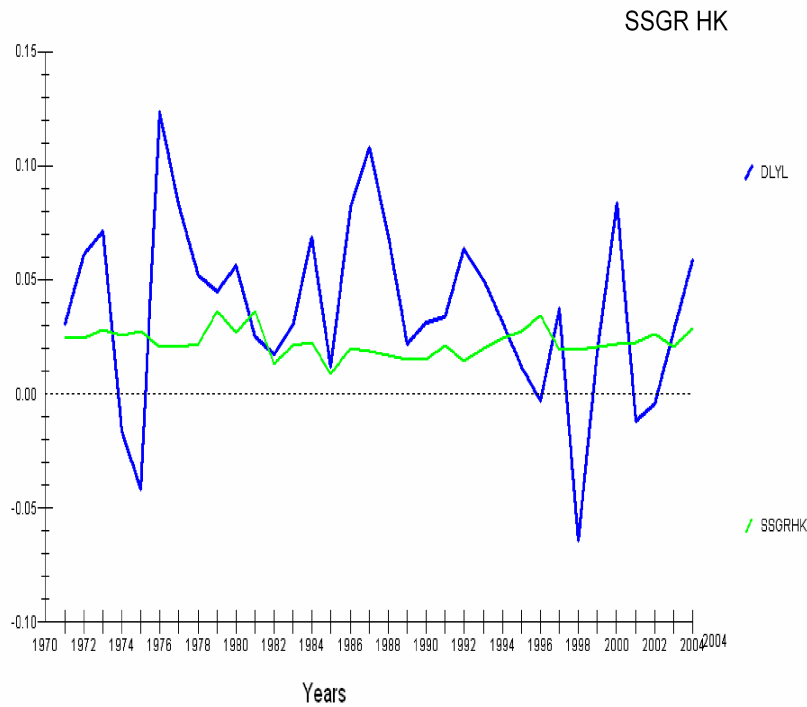

4.3 Hong Kong

In Hong Kong a profit share of 0.24 worked well and estimates are given in equation (VI) of Table 2. The implied SSGR is 2.4%. It can be seen from equation (VI) that the effect of TRADE and LBD on the SSGR are about equal. The average rate of growth of output per worker during 1970-2004 and 2000-2004 respectively are 3.7% and 3%, implying that Hong Kong is growing above its steady state growth rate. This may be due to some missing scale effects and/or due to the dynamic, but transient growth effects of the high investment rates in Hong Kong during the pre East Asian financial crisis. The average

investment rate has been about 30% with an average annual increase of 0.1%. After the Asian financial crisis, the decline in the investment ratio was more modest compared a decline of 56.5% in Singapore.¹⁸ Since trade openness is the highest in Hong Kong, where the mean value of TRADE is 2.280, its SSGR can be improved perhaps with more effective on the job training programmes. If ϕ can be increase by 25%, Hong Kong's SSGR can be increased to 3%. The SSGR for this country, with actual values of TRADE and employment growth, and the actual rate of growth of per worker income is in Figure 4. However, the SSGR showed a mild downward trend of -0.0001 .

Figure 4: Steady State Growth of Hong Kong

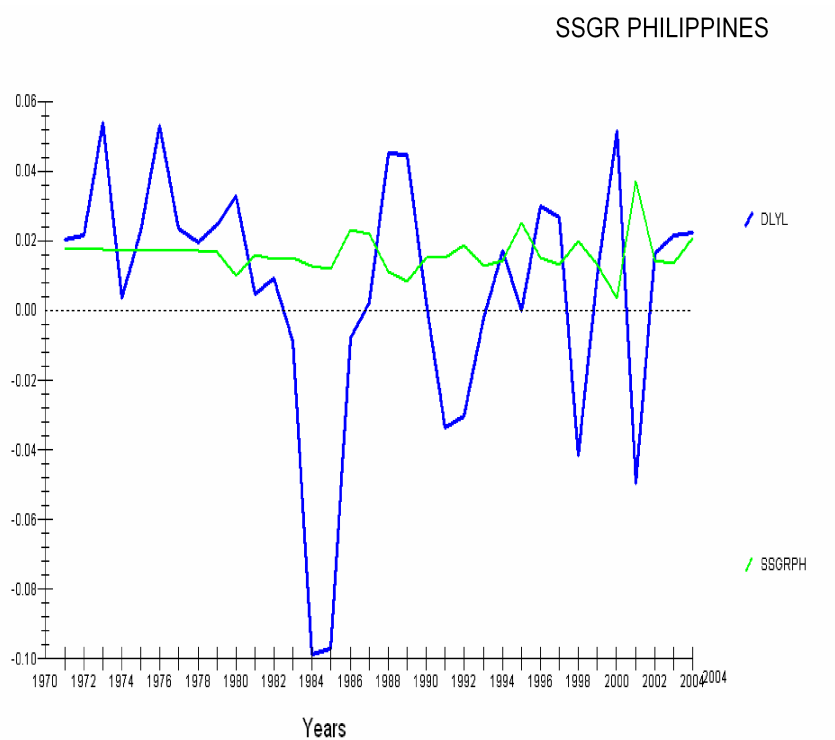

¹⁸The transient growth effects of changes in the investment ratio are not adequately recognized in empirical discussions. Simulations with the closed form solution of Sato (1963) show that such transient growth effects are significant and may last up to 20 to 25 periods.

4.4 The Philippines

Estimates for the Philippines are in equations (VII) of Table 2. The coefficient of TRADE, as well as the autonomous growth rate, in the specification of equation (16) were insignificant. Therefore (VII) is estimated with the constraints that g_1 and g_2 are zero. A profit share of 0.26 gave good results but the equation just passes the EM cointegration test at the 10% level. The absolute value of the t -ratio of λ of 3.23 just exceeds the absolute 10% CV in the EM test of 3.22.

Figure 5: Steady State Growth of the Philippines

Equation (VII) implies that Philippines' SSGR is 1.6% and it is entirely due to LBD. The average growth rate during 1970-2004 is 0.6% but this has doubled to 1.2% during 2000-2004. Yet this country seems to be growing below its steady state growth rate. Such a low steady state growth rate may be due to some negative externalities, especially due to the political instability and religious diversity in this country. Therefore, we cannot claim that our results for the

Philippines have adequately captured all the relevant externalities. Further work is necessary to draw definitive conclusions but it may be said that increased trade liberalization may make the coefficient of TRADE positive and significant. The SSGR for this country, with the actual values of employment growth, and output growth is in Figure 5. Like in Hong Kog there is a downward trend of -0.0002 in the SSGR.

4.5 Korea

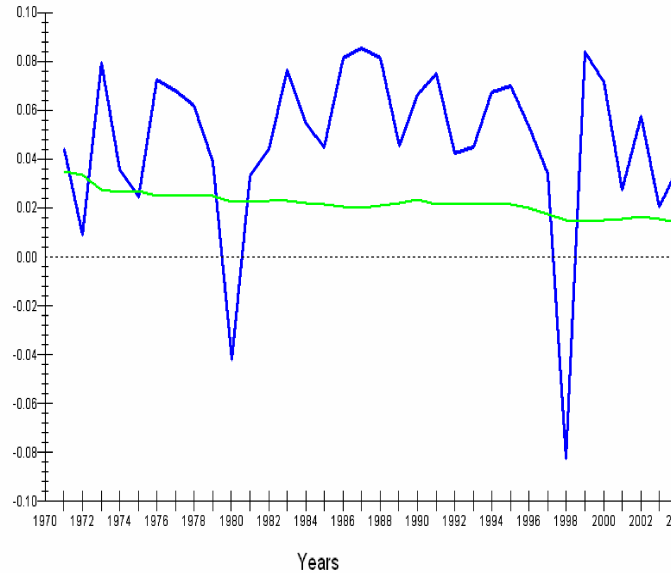

Finally, estimates for Korea are in equation (VIII) of Table 2. A profit share of 0.3 yielded good results and until the non-linear effects of trade were introduced the coefficient of TRADE remained insignificant. The non-linear effect is introduced with an inverse of the TRADE variable and implies that its growth effect on Korea's SSGR decreases as TRADE increases. The 5% level CV for the EM test is -4.269 and the estimated t -ratio of λ is -4.772 . Therefore, there is cointegration in this equation. The computed SSGR is 2.24%, which is similar to that of Thailand and a full one percent point less than in Singapore. TRADE is the major contributor with 1.3% points to SSGR which is about 60% of the SSGR. The actual average rate of growth of output at 4.7% is much higher than Korea's SSGR. Except during the late 1990s due to the financial crisis, from which Korea suffered very highly, Korea grew above its SSGR, due to the high rates of investment.

While Korea's trade openness has been increasing, its contribution to SSGR is declining. TRADE in 1970 was 0.34 and increased slowly to 0.84 by 2004. The decline in its effect on SSGR may be partly due to Korea's increasing reliance on domestic technologies and management practices.¹⁹

The declining trend in Korea's SSGR is shown in Figure 2 and seems to be due to two reasons. Firstly, as stated above, trade openness may not have played an effective role in the early stages of its development. As Korea became industrialized, protectionist pressures may have sheltered some inefficient domestic industries. Secondly, the

¹⁹There is some evidence that best technologies and management practices are not followed in Korea and there are some impediments to exit and enter into industries to insulate inefficient producers from market pressures; see Aw, Chung and Roberts (2003). There is also evidence to show that the mix of consumer goods changed to satisfy the domestic consumers and therefore seem to lack variety. During the early 1970s imports of consumer goods were slightly more than 20% and this has declined to less than 10% by the mid 1980s.

Figure 6: Steady State Growth of Korea

SSGR shown in Figure-6 depends on the actual rate of growth of employment and this has declined in Korea from a high of 3.5% during the 1970s to less than 1% by 2000.

To increase SSGR by another 0.5% points there are two options. First, Korea may increase its absorption of efficient technologies and management practices from the advanced countries. Second, Korea could improve its LBD programmes say by another 25% to achieve an additional 0.5% point increase in its SSGR.

5 Alternative Estimates of SSGRs

Our findings in the previous section are based on values of α found through the grid search method. If the true value of this parameter equals its stylized value of one third, our grid search causes slight over estimation of ϕ when $\phi < 1$ which in fact is the case. Consequently, SSGRs will be also over estimated.²⁰

To examine the sensitivity of the estimates of SSGRs and the relative importance of LBD and TRADE, we have re-estimated equation

²⁰ $\frac{\partial SSGR}{\partial \phi} = \frac{g+\phi n}{(1-\phi)^2} + \frac{n}{(1-\phi)} > 0$ for $\phi < 1$. Note that SSGR is not defined at $\phi = 1$, but it declines with increasing values of ϕ when $\phi > 1$.

(III) for Singapore and equations (IV) to (VIII) for the other countries with the assumption that $\alpha = 0.33$. The details of these estimates are not reported to conserve space but a summary is given in Table 3.

In the upper panel of Table 3, results with the estimated values of g_2 , ϕ and α (with grid search) of equations (III) to (VIII) are reported. The lower panel shows estimates of g_2 and ϕ from equations (III) to (VIII) with the assumption that $\alpha = 0.33$. The mean values of TRADE and the rate of growth of employment are used to compute SSGRs in both panels.

Table 3: Externalities in the Asian Countries

Variable	SGP	MAL	THA	HKG	KOR	PHL
Average $\Delta \ln y$	0.043	0.036	0.037	0.037	0.047	0.006
Average (I/Y)	0.325	0.247	0.342	0.280	0.312	0.182
Average $\Delta \ln L$	0.028	0.032	0.023	0.023	0.021	0.029
α (grid search)	0.240	0.250	0.240	0.240	0.260	0.300
\hat{g}	0.011	0.006	0.012	0.004	0.006	0.000
$\hat{\phi}$	0.220	0.312	0.285	0.292	0.289	0.357
$S\bar{S}GR$	0.032	0.015	0.023	0.024	0.022	0.016
Due to TRADE	75.63%	68.15%	51.56%	52.71%	61.61%	0.00%
Due to LBD	24.37%	31.85%	48.44%	47.29%	38.39%	100.00%
α (stylized)	0.330	0.330	0.330	0.330	0.330	0.330
\hat{g}	0.013	0.008	0.012	0.004	0.006	0.000
$\hat{\phi}$	0.153	0.058	0.242	0.242	0.265	0.352
$S\bar{S}GR$	0.032	0.013	0.020	0.022	0.021	0.015
Due to TRADE	84.09%	85.40%	56.47%	58.90%	64.54%	0.00%
Due to LBD	15.91%	14.60%	43.53%	41.10%	35.46%	100.00%

As indicated above a comparison between the upper and lower panel values of SSGRs shows that it is slightly over estimated with the grid search method. For Singapore and the Philippines this difference is small at about 2% and for Korea slightly higher at 3.7%. SSGRs for Malaysia, Thailand and Hong Kong this difference higher by 11%.

The relative importance of the contribution of TRADE and LBD to SSGRs qualitatively remains the same. However, for Malaysia the need to improve LBD policies increases substantially because its ϕ has now declined substantially from 0.132 to 0.058. Therefore, to increase Malaysia's SSGR by 0.5% points from 1.5% to 2%, the effectiveness of its LBD programmes needs to be improved by more than 50%.

6 Conclusion

In this paper we showed that the main advantage of the ENGMs, when estimated with country specific time series data, is that it is possible to estimate the SSGRs and offer policies to improve them. We showed how this can be achieved by estimating models for 6 Asian countries experiencing two externalities viz., LBD and TRADE. Our results showed that these externalities are significant in these 6 newly industrializing Asian countries, with the exception of the Phillipines where only LBD is significant. We have computed the SSGRs for these 6 countries and examined policies needed to improve these long run growth rates. The estimated SSGRs ranged from about 3% for Singapore to a low of 1.5% for Malaysia and the Phillipines. For Korea, Hong Kong and Thailand, SSGRs range from 2% to 2.5%. While the SSGRs for Singapore, Malaysia and Thailand showed a mild upward trend, in Hong Kong, Korea and the Phillipines the trend is downwards.

While the effects of both LBD and TRADE are found to be generally important in all the six countries, trade openness seems to have played relatively a dominant role in the progress of Singapore, Malaysia and Korea. In contrast, Phillipines seems to be a relatively closed economy and did not benefit from the potential externalities due to trade openness. However, LBD seems to be more important in the Phillipines, Thailand, Hong Kong and Korea followed by Singapore. Its effectiveness is low in Malaysia.

There is scope to improve the low SSGRs especially in Malaysia and the Phillipines. For example if LBD programmes are significantly improved, say by about 50%, in Malaysia its SSGR can be increased to about 2%. Similarly, if Phillipines introduces trade liberalization policies and they are effective at least with the same intensity in Malaysia, its SSGR can be improved to about 2%. Both Thailand and Hong Kong also have some potential to increase their SSGRs. Thailand needs to liberalize trade to absorb more efficient technolo-

gies and management skills. Hong Kong needs to improve its LBD programmes. The need to improve the already high SSGR of 3% of Singapore seems to be less urgent. Perhaps Singapore may ensure that its high SSGR can be sustained.

Needless to say there are some limitations in our paper. First, the structure of our model is simple and ignores factors that may have significant externalities and determine the SSGR. Second, we could not estimate the profit share parameter and employed a grid search method. However, in our view this may not be a serious limitation in that the assumed values for this parameter do not deviate significantly from the stylized value of one third which is frequently used in the growth accounting exercises. When the stylized value of one third is used for α , our estimates of the SSGRs did not change much especially for Singapore, Korea and the Philippines. The changes in the SSGRs for Malaysia, Thailand and Hong Kong are in the third decimal place. Third, there are alternative proxies for LBD and trade openness and it is desirable to use these alternative proxies to examine the sensitivity of our results. However, it is beyond the scope of the current paper. Fourth, we cannot claim that our model has adequately captured all the relevant externalities. Nevertheless, since the coefficient of trend was insignificant in all the equations, we can make a modest claim that our approach has adequately captured the growth effects of the missing trended growth improving variables. Finally, our model did not take into account externalities which need additional resources to improve TFP such as expenditure on R&D and education.²¹ But the effects externalities due to R&D are perhaps not important for the developing countries. They can use the vast amount of technology that already exists in the advanced countries. Perhaps development policy makers would pay attention to the factors that are hindering the utilization of improved technologies.

We hope that our approach and empirical findings would be useful for further extensions to the ENGM framework to develop policies to permanently increase the long run growth rates in other developing countries.

²¹Government investment on infrastructure is taken into account in our estimate of the capital stock.

Data Appendix

Y is the real GDP at constant 1990 prices (in million national currency). Data are from the UN National accounts database.

L is labour force or population in the working age group (15-64), whichever is available. Data obtained from the World Development Indicator CD-ROM 2002 and new WDI online.

URL:<http://www.worldbank.org/data/onlinedatabases/onlinedatabases.html>

K is real capital stock estimated with the perpetual inventory method with the assumption that the depreciation rate is 4%. The initial capital stock is 1.5 times the real GDP in 1969 (in million national currency). Investment data includes total investment on fixed capital from the national accounts. Data are from the UN National accounts database.

TRADE is computed as a ratio of exports and imports of goods and services on GDP. Data are obtained from UN's national accounts.

Investment ratio is computed as the ratio of total nominal investment to nominal GDP. Data are obtained from UN's national accounts.
