

Demand for Money in Developing Countries
Alternative Estimates and Policy Implications¹

Rup Singh and Saten Kumar

Suva, (Fiji)

Abstract

In this paper, we applied alternative time series techniques and obtained similar summaries of demand for money relations for twelve developing countries. This indicates that adequate attention should be paid to the purpose of research and interpretation of results rather than to econometric techniques. We also find that income elasticities are close to unity for almost all of our sample countries and the interest rate elasticities are well determined and significant. Further, it is shown that demand for money in these countries is temporally stable and therefore the respective monetary authorities may target money supply as opposed to the rate of interest.

1.0 INTRODUCTION

In empirical studies, controversy still persists on the relative merits of alternative time series techniques. While some prefer the systems based method of Johansen (JML), others are comfortable with the simpler single equation methods like the LSE-Hendry's General to Specific (GETS) and the Phillip-Hansen's Fully Modified OLS (FMOLS) approaches.² However, as Smith (2000) has pointed out, statistical techniques are only tools to summarize data and therefore they cannot answer difficult questions that need economic insights. Smith (2006) also notes that when the editors of the *Econometrics Journal* invited researchers (in 1995) to produce at least one paper, based on various econometric techniques, that shows that any existing economic theory needs substantial revision, none has been received to date. Therefore, it seems that existing theories can be applied without substantial revision and it is also doubtful if the alternative techniques give significantly different summaries. However, they may differ in their precision but only marginally. Thus, it is pointless to argue that one method is superior to another.

According to Smith there are three stages in applied works viz., purpose, summary and interpretation. A similar view is also taken by Rao (2006). It is noted that often applied economists neglect the first and third stages and pay too much attention to the econometric techniques. We show that alternative estimation methods give similar and consistent summaries of data. Therefore, we take the view that while it is desirable to use a few alternative methods of estimation, adequate attention should also be paid to the purpose and the need for preparing alternative summaries and their interpretations.

In this paper, we have used the money demand relation to provide some empirical support for this conjuncture. The three aforesaid techniques have been employed to estimate the short and long run relationships between the demand for narrow money and its determinants in 12 developing countries. Our sample countries with acronyms in

² For an interesting methodological debate on the relative merits of alternative time series approaches, see discussion in Smith (2000).

brackets are; Fiji (FJI), Vanuatu (VNT), Samoa (SAM), Solomons (SOL), India (IND), Indonesia (IDN), Philippines (PHL), Thailand (THA), Kenya (KEN), Malawi (MWI), Jamaica (JAM) and Rwanda (RWA). We also intend to examine if the income and interest rates elasticities differ significantly across these countries as some like India and Indonesia are very large with a large volume of transactions and others like Fiji, Samoa, Solomons and Vanuatu are small island countries. There are also medium sized countries like the Philippines, Thailand and Kenya. It would be interesting, therefore, to examine if the demand for money depends on the size of the country and the volume of transactions. This is of interest because, compared to the developed countries, cash is often used as the medium of exchange in the day to day transactions in many developing countries. Further, since the long and short run estimates are at hand, we also test if the money demand relations remains stable in light of the financial reforms in all these countries. This is important for policy because central banks in many developing countries have switched to interest rate as opposed to targeting the money supply. This is partly due to trailing the developed and advanced countries in targeting the rate of interest after the financial reforms. Further, the unit root and cointegration literature has made significant impact on modeling dynamic economic relationships especially on the demand for money.

The outline of our paper is as follows. In the next section, we specify the functional form and present our estimates of demand for money of the ample countries with the aforesaid techniques. In Section 3, we examine the temporal stability of these money demand functions and finally a summary of our interpretations with policy implications and conclusion are given in Section 4.

2.0 SPECIFICATION AND ESTIMATES

We use the standard Keynesian specification of demand for money in which demand for real narrow money is a function of real income and the nominal rate of interest. The interest rate measures the opportunity cost of holding money. Thus, our basic specification is:

$$\ln\left(\frac{M_t}{P_t}\right) = \beta_0 + \beta_1 \ln Y_t + \beta_2 R_t + \varepsilon_t$$

where M is narrow money consisting of currency in circulation and demand deposit, P is the GDP deflator, Y is real GDP measured at factor cost or market price, whichever is available, R is the nominal short-term interest rate on time deposits and ε_t is an iid error term. The exchange rate variable is ignored because currency substitution or having foreign currency accounts is illegal in these countries. Definitions of the variables and sources of data are in the appendix.

In what follows, we report the implied long-run elasticities and dynamic equations of demand for money for the sample countries and compare their results. However, before we detail our results, it is important to give a brief description of the alternative techniques.

The LSE-Hendry's GETS approach was developed before the present developments in time series methods. It does not conflict with the Cowles Commission approach since GETS is only an alternative but more attractive method of dynamic specification. It takes the view that it is hard to determine an equilibrium relationship with disequilibrium data collected from the world that is seldom in equilibrium. In addition, economic theory provides little guidance on how the dynamic adjustments take place. In the past, this gap was reconciled by the arbitrary lag specifications like Partial Adjustment Models and Almond lags, but these have limitations. As Rao (2005) explains, GETS determines the dynamic structure by using the data so that it is consistent with the underlying data generation process. Consequently, in GETS, a very general dynamic lag structure between the dependent and explanatory variables consisting of their lagged levels and first differences is estimated³. This overly long general unrestricted model (GUM, for

³ However, a standard but somewhat unjustified criticism against GETS is that it specifies an unbalanced equation with both I(0) and I(1) variables. In response, Hendry repeatedly states that if the economic theory is correct, the levels part of GETS should be cointegrated and the linear combination should be stationary. Thus, the unit root literature has little implications for GETS.

short) is reduced into a manageable parsimonious version by applying the standard variable deletion tests while ensuring that the residuals satisfy the underlying classical assumptions. A good exposition of GETS can be found in Charemza and Deadman (1997). However, although this may sound simple, GETS is computationally demanding if the GUM has a large lag structure.⁴

The Johansen cointegration (JML) is a variant of the VAR approach. However, unlike VAR, in JML, all coefficients are identified and close attention is paid to the underlying economic theory. It is also the most widely used approach in applied time series studies and the routines are found in most econometric software. In JML, pre-testing of variables for unit root is important and all variables are assumed to be endogenous before exogeneity is confirmed with formal tests. The test for the existence of the cointegrating vector(s) are conducted with a procedure that allows for (un)restricted intercept and restricted/no trend options for the VAR. In the JML, the null of no cointegration can be rejected/not rejected with the computed eigenvalue and trace test statistics which are detailed in standard econometric texts or software manuals. The exogeneity tests for block Granger Non-Causality with the null that the coefficients of the lagged values of dependent variables are insignificant in the equations of independent variables are conducted. The computed LAR test indicates if there is endogeneity bias, i.e whether the dependent variable Granger causes the independent variable(s)⁵. Identification is tested by regressing the first difference of each variable on the one period lagged residuals normalized on respective variables. It is confirmed if respective ECMs are significant with correct negative signs in their own equations.

The Phillip-Hansen's FMOLS procedure is developed to account for possible correlation between the regressors and the residuals as the asymptotic distribution of OLS is non-standard. Therefore, inferences based on the usual t-tests may be invalid without this adjustment. The FMOLS is a two step procedure and is less flexible than GETS and JML.

⁴ In this respect, Hendry and Krolzig's PcGets - an automatic model selection software- may be useful, see Rao and Singh (2005b) for an application of PcGets in demand for money in Fiji.

⁵ As explained by Rao (2005), the Granger causality test is not a cause and effect test but a test of precedence and in itself does not indicate causality used in the more common sense.

In the first stage, the cointegrating coefficients are estimated in levels of the $I(1)$ variables. Thus, pre-testing is also required in FMOLS. Standard econometrics software manual has the routines for this procedure. However, there is some flexibility in selecting the lag lengths of the VAR, but the Microfit manual suggests the Parzen lag structure. One may also try with smaller lags and increase them systematically by keeping track of the estimated coefficients and stop varying the lags when there are no significant changes in the estimates.

If there are no serious endogeneity problems, GETS and JML results should be consistent with FMOLS. While these three approaches, GETS, JML and FMOLS are similar, GETS is based on single equation approach with the presumption of a unique cointegrating vector and exogeneity of the explanatory variables as implied by the underlying economic theory. Such assumptions are also made in FMOLS and it is simpler to implement than GETS or JML. In contrast, the JML is a systems based approach and it offers a more unified framework for estimating and testing cointegrating relationships in the context of ECMs. However, sometimes, JML yields unsatisfactory cointegrating relationships and therefore, it is important to apply more than one method often to check for consistency between them. Our experience has shown that information from GETS is useful for the JML procedure. Also, in a three equation system there could be more than one but at most two cointegrating vectors (CVs). In such a situation, the choice of the relevant CV should be made with reference to the underlying economic theory and by evaluating the signs and magnitudes of the respective implied long-run coefficients. However, if both CVs are plausible, a two equation system must be estimated by imposing cross-equation restrictions. This calls for a VAR approach which is computationally demanding when data points are limited. Nonetheless in all approaches, GETS general-to-specific philosophy is applied in estimating the dynamic structure.

In Table-1, we report the cointegrating coefficients obtained with alternative approaches of GETS, JML and FMOLS, respectively. The GETS implied long-run estimates are in the first three columns. The next three are for JML and FMOLS, respectively, which are obtained after we subjected the variables to unit root tests. The test results are in

Appendix. Note, that the implied income ($\beta_1 Y_t$) and semi-interest rate elasticities ($\beta_2 R_t$) are similar for all countries across all the three approaches. Except for the Philippines where income elasticity is around 1.25, we obtained unit income elasticities for all other countries. The Wald tests on the null of unit income elasticities were not rejected at 5% for all countries⁶. The implied semi-interest rate elasticities vary from country to country, but have the expected negative sign and are significant. The sample average of the implied long-run interest rate elasticities, at their mean rates are; -0.256 in GETS, -0.369 with JML and -0.298 with FMOLS. The income elasticities indicate the financial systems in these countries are less efficient than the developed nations and the interest rate elasticities indicate a weak linkage to the bonds market which in many of these economies is in the embryonic stage. These results are comparable to Sriram (1999) for developing countries, Oskooee and Rehman (2005) for Asian economies, Rao and Singh (2005a & 2005b) for Fiji and India, respectively, Pradhan and Subramanian (2003) for India, Hafer and Kutan (2003) for Philippines.

Notes:

1. The income and semi-interest rate elasticities are given as β_Y and β_R , respectively and all are significant at 5%, except for in the JML β_R for SOL and MWI are significant at 10% level. The absolute t-ratios are in brackets.

2. Sample periods are: FJI:1976-2002, VNT:1978-03, SAM: 1982-02, SOL:1978-02, IND:1873-02, PHL:1981-02, IDN:1975-04, THA:1982-04, KEN:1971-04, JAM:1978-03, RWA:1984-03 and MWI:1981-04.

3. Based on Ericsson and MacKinnon (2002) tests for finite samples, the null of no cointegration was rejected at 5% in GETS and FMOLS for all the countries, except for SOL (in FMOLS) and IND (in GETS) where it was rejected at 10% level. However, the test indicated no cointegration for SOL and MWI in GETS. Nevertheless, the Eigenvalue and Trace tests in JML indicated cointegration for all countries at conventional levels. Details of these tests are available from the authors.

However, as is required, we subjected the CVs obtained in JML to further tests. The identification tests indicated that the implied long-run relations represents demand for money functions, for each country, since only the one period lagged residuals normalized on $\ln(M/P)$ were significant with correct negative signs in their respective $\Delta \ln(M/P)$ equations. Further, the Enders (2004) weak exogeneity testes implied that the disequilibrium in the respective money markets do not significantly contribute to the explanation of $\ln Y$ and R in all cases. Therefore, we treated real output and the rate of interest as weakly exogenous in the respective money demand equations⁷.

The dynamic money demand equations for each country for JML and FMOLS were estimated by using the general to specific philosophy to search for the best lag structure. Note in GETS, both the equilibrium relation and the dynamics are estimated in one step.

⁷ In the identification tests, both the one period lagged residuals normalized on income and the rate of interest were insignificant in their respective regressions. Details for both tests are avoided for brevity, but are available from the authors upon request.

However, it is not pragmatic to report all these estimates in this paper. Thus, we only report the JML dynamic specifications in Table-3(a), 3(b) and 3(c) as JML seems to be the widely used approach in applied works. This does not imply that JML is superior to others. The dynamic estimates in GETS and FMOLS are comparable to JML and in some cases gave marginally better results⁸. In all these tables, the chi-square tests (in order of presentation) are for the null of serial correlation, functional form mis-specification, non-normality in residuals and heteroscedasticity and none are significant at 5% level. The absolute t-ratios are in parenthesis below the coefficients and those reported below the chi-square tests are the p-values. Significance at 5% and 10% are indicated with * and **, respectively.

Table-3(a) includes estimates for Fiji, Vanuatu, Philippines, and Solomon's. Their unconstraint estimates are given as (i) and with some valid coefficient restrictions, which were subjected to Wald tests, are reported as (ii). For Fiji, DUM1 captures the effects of the two political instabilities of 1987 and 2000. It has a positive coefficient because the coup is likely to increase holdings of precautionary balances. DUM2 resembles the combined effects of two devaluations and the NBF crisis in Fiji which has negative effects. For Vanuatu and Philippines, DUM2 represents the financial sector reforms which has positive impact as better and efficient financial systems allow improved availability of credit.

X^2_n	1.320 (0.52)	1.414 (0.49)	0.735 (0.69)	0.981 (0.61)	1.808 (0.41)
X^2_{hs}	0.132 (0.72)	0.115 (0.74)	0.408 (0.52)	0.320 (0.57)	0.307 (0.58)

Note for all the dynamic estimates reported above, the χ^2 summary statistics are insignificant at 5% level. For Fiji, Kenya and Thailand the functional form is significant at 10% but not at 5% level. The SEEs in all estimates are reasonable and the lagged ECM terms are strongly significant with correct negative signs. Regression between the actual and fitted values of the change in logarithm of real money show good fit of data. Details are avoided to conserve space.

4.0 STABILITY AND POLICY IMPLICATIONS

We tested for temporal stability of the preferred estimates using the TIMVAR tests and neither the CUSUM nor the CUSUM SQUARES showed any instability. The stability test results (CUSUM SQUARES only) are reported in the Appendix⁹. These results together with Poole's (1970) conjuncture on the choice of appropriate monetary policy instrument implies that targeting the rate of interest may cause more volatility in income levels. For the respective monetary authorities in these countries, targeting money supply is optimal because their money demand relations are stable. Further, we argue that although there have been some financial innovations in these economies, the money demand relation has remained stable because it is hard to quickly change the nature of the day-to-day exchange patterns based on the use of cash.

5.0 SUMMARY AND CONCLUSIONS

In this paper, we have applied three alternative time series methods and obtained similar and consistent cointegrating coefficients for all the sample countries. This indicates more emphasis should be placed on the economic interpretation of results rather than the estimation methods because it is highly unlikely that alternative methods will give conflicting results. However, notwithstanding the relative merits/de-merits of each approach, one should adopt a method that is simple to implement and gives reasonable summaries of observed facts because ultimately, no single approach is capable of explaining all the reality that we aspire to unveil. In this respect, we must not lose sight of the purpose of research and interpretation of results. Third, our results show that the estimated income and interest rate elasticities are well determined and their signs and magnitudes are consistent with *prior* expectations. The income elasticities are unity in all the three approaches for all countries in our sample, except for the Philippines where it is slightly higher at 1.25, and the interest rate elasticities are small and negative varying slightly across countries. Finally, we found that demand for money in these countries is

⁹ The CUSUM results are not reported to conserve space, but are available from the authors upon request.

stable and therefore, money supply is the appropriate monetary policy target for central banks.

A few limitations of our work should be noted. We have ignored the structural breaks and their implications on unit roots and cointegration tests. Although, we are aware of endogenous break tests of Gregory-Hansen (1992) and Bai-Perron (2003), we are faced with practical problems in utilizing these tests with a limited number of annual observations relative to the number of such possible breaks, see Rao and Singh (2005a) for a discussion on the break point tests. Nonetheless, we have conducted the usual CUSUM and CUSUM SQUARES stability tests which indicate that all the estimated equations are stable. We are hopeful that our work will be useful especially to applied economists in selecting alternative techniques for further works on important relationships such as demand for money.

Data Appendix

P = GDP deflator (2000=100). Data derived are from International Financial Statistics (IFS-2005).

Y = Nominal GDP at factor cost or market prices, whichever is available. Data are from IFS-2005.

R = The average short-term (maximum of 3 years) savings deposit rate. Data derived from the IFS-2005 and ADB database (2005).

M = Currency in circulation, including demand deposit and bills payable. Seasonally adjusted data obtained from IFS-2005.

Notes:

1. All variables, except the rate of interest, are deflated with the GDP deflator and are in natural logs.
2. Data are available for replication on request.

Table-2: ADF Unit Root Tests

	Lags	$\ln M_t$	$\Delta \ln M_t$	$\ln Y_t$	$\Delta \ln Y_t$	R_t	ΔR_t
FIJI	[2,1,1,0,3,0]	2,354	5.908	1.422	9.073	0.777	6.328
VNT	[0,0,1,0,1,1]	1.172	5.667	1.171	3.844	1.158	6.555
SAM	[1,1,1,0,1,0]	1.479	3.756	2.186	4.218	1.378	4.472
SOL	[0,0,1,0,2,0]	1.403	5.228	1.503	3.324	1.222	4.098
IND	[0,2,1,0,1,3]	0.790	5.792	0.346	8.914	0.293	3.711
PHL	[0,0,1,1,3,3]	2.370	5.869	2.573	3.964	2.746	3.638
IDN	[2,1,2,1,2,0]	2.612	7.081	0.053	5.747	1.739	5.500
THA	[0,1,1,1,3,1]	1.311	5.245	1.679	4.618	1.653	4.020
JAM	[0,0,1,0,0,0]	1.778	6.407	2.563	3.618	1.467	7.945
KEN	[0,0,1,3,3,1]	1.519	7.976	2.239	6.075	0.360	4.313
RWA	[0,0,0,0,3,3]	2.032	4.611	1.964	4.772	0.826	3.904
MWI	[1,2,0,0,0,0]	1.254	3.756	2.598	7.328	2.263	3.719

Notes:

1. $\ln M_t$ and $\ln Y_t$ represent log of real money and real income, respectively. $\ln P_t$ is stationary for India, Rwanda and Malawi and there is no need to proceed further for this variable.
2. The respective 1% and 5% critical values for ADF test are 3.685 and 2.970.
3. Lag lengths are for the respective variables selected with AIC and SBC criteria. For example [0,1] indicates that lag 0 and 1 are significant in 1st and 2nd columns, respectively.
4. The sample period are: India(1973-2002), Kenya(1969-2004), Fiji(1976-2002), Vanuatu(1978-2003), Indonesia(1975-2004), Jamaica(1980-2003), Samoa (1982-2202), Solomon(1979-2002), Philippines and Malawi(1979-2004), Thailand(1983-2004) and Rwanda(1982-2003).
